Abstract
The synthesis of 1,4-dihydropyridine (1,4-DHP) derivatives in the presence of alkaline earth metal chlorides was reported. Specifically, the MgCl$_2$ catalyzed the synthesis of 1,4-DHP derivatives in good yields, ranging from 69 – 87%. The Mg$^{2+}$ serves as the Lewis acid catalyst in the formation of 1,4-DHP and the proposed mechanism of the formation of 1,4-DHP was elaborated in this manuscript. There are many advantages employing MgCl$_2$ as a catalyst in this study, including inexpensive, ubiquitous availability of this metal, simple filtration protocol, which has sparked considerable interest in the use of this catalyst in promoting organic reactions.

Keywords: alkaline earth metal, magnesium chloride; 1,4-dihydropyridine

Abstrak
Sintesis terbitan 1,4-dihidropiridina (1,4-DHP) dalam kehadiran logam alkali bumi dibincangkan dalam artikel ini. Secara khususnya, sintesis terbitan 1,4-DHP melalui pemangkin MgCl$_2$ memberi peratusan hasil yang baik, dalam lingkungan 69 – 87%. Ion Mg$^{2+}$ bertindak sebagai pemangkin asid Lewis dalam pembentukan 1,4-DHP dan cadangan mekanisma terhadap pembentukan 1,4-DHP telah dihuraikan dalam manuskrip ini. Terdapat banyak kelebihan menggunakan MgCl$_2$ sebagai pemangkin dalam kajian ini, termasuk kos yang murah, ketersediaan logam ini, protokol pengekstrakan yang mudah, yang mana ini telah mencetuskan minat yang besar dalam penggunaan pemangkin ini dalam pelbagai tindak balas organik.

Kata kunci: logam alkali bumi, magnesium klorida; 1,4-dihydropiridin

Introduction
1,4-dihydropyridines (1,4-DHPs) are important classes of pharmaceutical compounds that are usually prescribed clinically for the treatment of cardiovascular diseases, such as heart failure, angina pectoris and hypertension [1]. In the pharmaceutical pipeline today, there are more than twelve 1,4-DHPs drug candidates commercially available in the global market, such as the nifedipine [2], felodipine [3], nicardipine [4] and etc., which were used to treat cardiovascular diseases.
Due to the attractiveness of the 1,4-DHPs in pharmaceutical application, various synthetic approaches to produce 1,4-DHP derivatives have been reported, such as the use of microwave irradiation [5], solar thermal energy [6], ultrasound irradiation [7], ionic liquids [8], and AlCl₃ as Lewis catalyst [9]. In spite of the above efforts to improve further on the 1,4-DHPs reactions, a number of drawbacks have been identified such as unsatisfactory yields, high reaction temperatures and long reaction hours [10].

Recently, there are a number of literatures reported on the use of alkaline earth metals for organic transformations. For instance, MgCl₂ has been successfully employed for the aldol synthesis of α-dimethylsilylesters [11]. An improved method on the Biginelli reaction by using alkaline earth metal chlorides such as MgCl₂, CaCl₂, BaCl₂ and SrCl₂ as homogenous catalysts in the presence of acetic acid as solvent had been reported [12]. The synthesis of dihydropyridine, acridine and xanthene derivatives with Ca(OTf)₂ in the presence of Bu₄NPF₆ as additive and water as solvent has also been disclosed recently [13]. The alkaline earth metals are the most abundant elements encountered in our daily lives in which most of it can be found buried in the earth crust and in the ocean [14]. On green chemistry perspective, the use of alkaline earth metals in organic reactions are favorable due to the fact that, metals such as calcium and magnesium are ubiquitously available in nature compared to other transition and lanthanide elements [15]. However, only limited organic reactions which employ alkaline earth metals as catalysts were reported as their applications are not being fully explored [16].

In the course of our research to synthesize bioactive heterocyclic compounds, herein we report the synthesis of 1,4-DHP derivatives catalyzed by MgCl₂ from the starting materials benzaldehydes, ethyl acetoacetate and ammonium acetate (as shown in Scheme 1). The advantages of this protocol include the exclusion of additional additive, for example Bu₄NPF₆ and the reaction could be accomplished within four hours. The synthesized products were obtained in good yield as described in this paper.

Scheme 1. The MgCl₂ catalyzed the synthesis of 1,4-DHP derivatives

Materials and Methods

All the chemicals and solvents used without further purification in this study are supplied by Merck, Acros organic and HmbG® chemicals. These include benzaldehyde, 4-fluorobenzaldehyde, 4-chlorobenzaldehyde, 4-nitrobenzaldehyde, 4-bromobenzaldehyde, ethylacetoacetate, ammonium acetate, methanol, ethyl acetate, n-hexane and silica gel 60 (0.063-0.200mm). The FT-IR spectra were recorded on Perkin Elmer 100 FT-IR spectrometer, in spectral range of 4000 – 400 cm⁻¹. ¹H and ¹³C-NMR spectra were recorded using Bruker Avance III 400 spectrometer, with deuterated chloroform as solvent at room temperature at 400 MHz. GC-MS analyses were performed using Shimadzu QP2010SE.

Synthesis of the 1,4-DHP derivatives

To a mixture of benzaldehyde derivatives (1.47 mmol), ammonium acetate (1.47 mmol), and ethyl acetoacetate (1.47 mmol) in methanol (3 ml), MgCl₂ was added (0.15 mmol) and the mixture were heated under reflux for four hours. After the completion of the reaction, the solvent was evaporated under reduced pressure to obtain the crude product. The crude product was then purified over silica gel column chromatography (hexane: ethyl acetate = 7:3, v/v) to give the title compounds 1a-1k.
Results and Discussion

The optimized condition was determined using a model reaction that consisted of benzaldehyde, ethyl acetoacetate and ammonium acetate. The model reaction was first conducted without adding any catalysts, recorded only 30% yield after the reaction was heated under reflux for four hours in methanol. The use of catalytic amount of MgCl₂ greatly enhanced the yield of the desired product and the best yield was recorded with the use of 5 mmol of MgCl₂ which afforded 87% yield of the desired product. Next, the study of using various alkaline earth metals in different solvents was evaluated. Based on the optimization study (Table 1), the maximum yield of 1a was recorded when the reaction was heated under reflux for four hours in the presence of 5 mmol of MgCl₂ as catalyst in MeOH.

The improved protocol was employed to synthesize different substituted 1,4-DHP derivatives by using a variety of benzaldehydes. As shown in Table 2, all the reactions proceeded smoothly in the presence of MgCl₂ and the desired products were isolated in moderate to good yields, ranging from 69 – 87%. The electronic effect of different substituted groups on benzaldehydes was also evaluated. Specifically, the benzaldehydes bearing the electron-withdrawing group gave a higher yield compared to benzaldehydes bearing electron-donating group (Table 2, 1b -1j vs 1k). This result was in agreement with a previous study on the synthesis of the 1,4-DHP derivatives using ultrasound method [17]. Among the investigated electron-withdrawing substituents, the para- position gave a higher yield compared to ortho- and meta- position (Table 2, 1b -1e vs 1f-1j). In the previous study, the side products (Figure 1) were usually yielded along with the desired products [17]. Gratifyingly, under this improved protocol which utilized MgCl₂ as catalyst, only one 1,4-DHP derivative was isolated for each reaction, with no side products isolated during the purification process in the column chromatography.

The side products, 2 and 3 were reported to be produced from the Hantzsch 1,4-dihydropyridine synthesis [17].

The proposed mechanism for the formation of 1,4-DHP catalyzed by MgCl$_2$ was elaborated in Scheme 2. Firstly, one equivalent of ethyl acetoacetate reacted with benzaldehyde to form the knoevenagel adduct and one equivalent of ammonium acetate reacted with ethyl acetoacetate to form ester enamine. Subsequently, the Michael-type addition and condensation occurred to yield 1,4-DHP derivative as the final product. The Mg$^{2+}$ serves as the Lewis acid catalyst in the formation of 1,4-DHP derivatives.

**Physical and spectral data**

The spectroscopic data of the synthesized compounds 1a – 1k is as follows:

GC-MS: m/z 371 [M+H]⁺.

There are many advantages of using MgCl₂ in the Hantzsch dihydropyridine synthesis, including the simple separation process, mildness of this technique, no side products and good yields. The alkaline earth metals are inexpensive, especially MgCl₂ which can be found ubiquitously buried in the earth’s crust. Although various literatures have been generated with respect to the synthesis of 1,4-DHP derivatives, most of these methods relied on the use of expensive chemicals, toxic chemicals or harsh condition.

Conclusion
A simple, mild and high yielding protocol for the synthesis of 1,4-DHP derivatives catalyzed by MgCl₂, an alkaline earth metal has successfully developed. The mildness of this technique, experimental simplicity and the inexpensive of this catalyst have rendered this protocol an attractive way for the synthesis of 1,4-DHP derivatives. Furthermore, this heterogeneous catalyst can be easily removed with simple filtration technique. Further application using alkaline earth metals in other organic reactions are continuously been explored in our laboratory.
